Abstract For a class of scalar nonlinear systems with switching input a controller is designed using design theory for linear systems. A stability criterion is derived that contains all the physical system parameters, allowing a stability analysis without the need for numerical simulation. The results are motivated by and applied to a model of a bulk storage room for food products. It is shown that for this model a controller with excellent robustness and performance properties can be designed.

1 Introduction

Climate control is an essential part of post-harvest food storage. For maintaining optimal product quality, the most important control parameters are temperature, humidity, CO₂ concentration and ethylene concentration inside the storage room. The most common control inputs are ventilation, cooling, heating, and (de)humidification. The storage room can be ventilated in two ways: ventilation with outside air, or recirculation inside. Forced ventilation is done by fans. Cooling and heating is done by outside air ventilation or by a heat exchanger, and CO₂ and ethylene concentrations are controlled by outside air ventilation. The corresponding mathematical models have complex dynamics due to the airflow and heat- and moisture exchange. Some control inputs are of a discrete nature. Forced air ventilation, for example, is usually realized by a fan that is switched on or off. Generally, standard linear model-based control design is preferred, since it is a mathematically well-understood and practically implementable method, but given the nonlinearities due to the switching input, it is not feasible for this class of systems.

Control strategies that have been developed for storage purposes, are model predictive control (MPC) and fuzzy control. In [5] and [13], MPC algorithms were used for the temperature and humidity control of a bulk storage room with outside air ventilation. Both proposed algorithms are model based and were tested by simulation studies. In [1] a fuzzy controller was tested on a mathematical model. In [3] a sensor based control law for a bulk storage room that was ventilated with outside air was proposed, and in [2] a fuzzy controller was constructed and tested experimentally. In [10] a fuzzy controller was devel-
oped for fruit storage, using neural networks, and in [9] a fuzzy controller was tested experimentally. Further, in [8] a PI controller was designed for CO$_2$ and O$_2$ concentrations, and was tested experimentally. In general, the advantages of MPC are that the control algorithm is based on a mathematical model, and that the applicability extends to extremely complicated models. A major drawback is that controller dynamics have to be solved by demanding online numerical computations. Fuzzy controllers are practically easy implementable, but have no mathematical background, and hence controller performance is hard to guarantee.

More general, control design for systems where the switching input is the control parameter, is done by MPC and fuzzy control, as shown above, and switching adaptive control. Stabilizing adaptive controllers are designed in [15, 4] for a large class of nonlinear MIMO systems and for a larger class of MISO systems in [6], with less restrictive assumptions. Here, the control input is switched between two functions that depend continuously on the system states.

In this paper, a controller is designed for a class of piecewise linear systems with switching control inputs. The inputs have fixed values, and are switched at most once in each discrete time interval, in contrast to for example [15, 4, 6]. This paper is organized as follows. In section 2 the model is linearized to a system with the switching moment as input. A controller that dynamically adjusts this input, is designed using standard design theory for linear systems. In section 3 conditions for stability are derived. The stability region is a parametric function of all the system properties, which makes analysis easier. In section 4 the theoretical results are applied to a model of a bulk storage room for harvested products. The control input of this model is the air flow induced by the fan, which is switched on and off on a regular basis. It is shown that the errors that are induced by the linearization cannot destabilize the system. The performance loss due to the linearization is visualized by numerical simulation of the original p.d.e. model, and the approximated piecewise linear system. Both systems are connected to the controller, and simulated under a heavy input disturbance. Since the dynamics of both systems are essentially the same, it is concluded that no essential dynamics are lost, and hence for this model a controller with excellent properties can be designed.

## 2 System approximation and controller design

Our class of systems is nonlinear, scalar SISO systems of the form

$$\frac{dx}{dt} = A(u)x + B(u).$$

(1)

Here, $x$ is the system state, $u = (u_1, u_2)$ the input that attains two discrete values, and $A$ and $B$ scalar functions. The continuous time is divided into discrete time intervals with length $\tau_f$. The control problem is to determine the duration of both inputs. We assume, without loss of generality, that at the start of each time interval $u = u_1$. The input is switched from $u_1$ to $u_2$ at time $\tau$, 
with $0 \leq \tau \leq \tau_f$. This gives the following piecewise linear system

$$\frac{dx}{dt}(t) = A(u_1)x(t) + B(u_1) \quad t \in [0, \tau),$$  \hspace{1cm} (2)

$$\frac{dx}{dt}(t) = A(u_2)x(t) + B(u_2) \quad t \in [\tau, \tau_f),$$  \hspace{1cm} (3)

with $x(\tau^-) = x(\tau^+)$. From now on, the notation $A(u_1) = A_1$ is used, and the subscript denotes the relation with the input. Now $\tau/\tau_f$ is the fraction of the time that $u = u_1$. The goal is to design a controller that steers $x$ to the desired state $x_{opt}$ by adjusting $\tau$ each time interval. Although we want to steer $x(t)$ to $x_{opt}$, the control action is only based on the state at the beginning of each time interval. Therefore in the following sections we design a sequence of switching times $\tau \in [n\tau_f, (n + 1)\tau_f)$, based on $x(n\tau_f)$ and previous samples, such that $x(n\tau_f) \to x_{opt}$ for $n \to \infty$. If the sample time $\tau_f$ is small, then this implies that $x(t) - x_{opt}$ will be small for large $t$. Hence in practice this gives that the state is stabilized around $x_{opt}$.

Throughout this paper, we assume that $A_1$ and $A_2$ are negative, and that $A_1^{-1}B_1 > A_2^{-1}B_2$. Since the choice of $A_1$, $A_2$ in (2)–(3) was arbitrary, this imposes no real restrictions.

### 2.1 System approximation

In this section, the system is approximated, and a controller is designed using standard design theory for linear continuous systems. At the interval $(0, \tau_f)$, the solution to equation (2) at time $\tau$ is

$$x(\tau) = x(0)\exp(A_1\tau) + \int_0^\tau \exp(A_1(t - \tau))B_1\,dt$$

$$= x(0)\exp(A_1\tau) - \left(I - \exp(A_1\tau)\right)A_1^{-1}B_1.$$  \hspace{1cm} (4)

Similarly, the solution to equation (3) becomes

$$x(\tau_f) = x(\tau)\exp(A_2(\tau_f - \tau)) - \left(I - \exp(A_2(\tau_f - \tau))\right)A_2^{-1}B_2.$$  \hspace{1cm} (5)

In the interval $[n\tau_f, (n + 1)\tau_f]$ we choose the switching time $\tau^n$. We denote the state at time $n\tau_f + \tau_n$ by $\xi^n$ and the state at the time $n\tau_f$ by $x^n$. So we have

$$\xi^n = \exp(A_1\tau^n)x^n + (\exp(A_1\tau^n) - 1)A_1^{-1}B_1$$

$$x^{n+1} = \exp(A_2(\tau_f - \tau^n))\xi^n + (\exp(A_2(\tau_f - \tau^n)) - 1)A_2^{-1}B_2.$$  \hspace{1cm} (6)

Combining the equations in (6), we find that

$$x^{n+1} = f(x^n, \tau^n).$$  \hspace{1cm} (7)

The switching time is chosen such that the system is in the desired state $x_{opt}$ for all time instances $n\tau_f$. The following lemma shows that for any $x_{opt} \in [-A_1^{-1}B_1, -A_2^{-1}B_2]$ there exists a unique switching time $\tau_{opt} \in (0, \tau_f)$ such that

$$x_{opt} = f(x_{opt}, \tau_{opt}).$$  \hspace{1cm} (8)
Lemma 2.1. Consider the system (6). Then equation (8) has a solution \( \tau_{opt} \in [0, \tau_f] \) if and only if

\[
-A_1^{-1}B_1 \leq x_{opt} \leq -A_2^{-1}B_2. \tag{9}
\]

Furthermore, when (9) holds, then the solution \( \tau_{opt} \) is unique.

Proof. See the appendix.

Since we will not start at \( x_{opt} \) and since disturbances may drive \( x \) away from the desired state \( x_{opt} \), we want to design a feedback control law for \( \tau_n \), such that \( x^n \to x_{opt} \). For this we linearize system (7) around \( x_{opt}, \tau_{opt} \), i.e. we set

\[
\tau^n = \tau_{opt} + \tau_{var}^n,
\]

\[
x^n = x_{opt} + x_{var}^n. \tag{10}
\]

The linearized system equals

\[
x_{var}^{n+1} = \frac{\partial f}{\partial x_n}(x_{opt}, \tau_{opt})x_{var}^n + \frac{\partial f}{\partial \tau_n}(x_{opt}, \tau_{opt})\tau_{var}^n
\]

\[
= A_d x_{var}^n + B_d \tau_{var}^n. \tag{11}
\]

We have that

\[
A_d = \exp(A_2(\tau_f - \tau_{opt}) + A_1 \tau_{opt})
\]

\[
B_d = -A_2 \exp(A_2(\tau_f - \tau_{opt}))\xi(\tau_{opt})
\]

\[
+ \exp(A_2(\tau_f - \tau_{opt}))(A_1 \exp(A_1 \tau_{opt})x_{opt} + B_1 \exp(A_1 \tau_{opt}))
\]

\[
- B_2 \exp(A_2(\tau_f - \tau_{opt}))
\]

\[
= -A_2 x_{opt} - B_2 + \exp(A_2(\tau_f - \tau_{opt}))(A_1 \exp(A_1 \tau_{opt})x_{opt} + B_1 \exp(A_1 \tau_{opt})). \tag{12}
\]

Since \( A_1 \) and \( A_2 \) are negative, and since \( 0 \leq \tau_{opt} \leq \tau_f \), we see that \( A_d \in (0,1) \). We note that any nonlinear MIMO system with switching input can be brought to the form of (11), and hence enable linear (discrete) control design. However, we consider scalar systems of the form (1) since they allow a rigorous stability analysis that results in a stability area that consists of analytical expressions that contain physical knowledge of the system.

2.2 Controller design

In the appendix we show how by using a standard PI controller on an approximate continuous time system, a controller can be designed for our discrete time system. Our PI-based controller in discrete time is

\[
\zeta^{n+1} = \frac{(A_d - 1)^2}{B_d} x_{var}^n + \zeta^n
\]

\[
\tau_{var}^n = \frac{A_d - 1}{B_d} x_{var}^n + \zeta^n. \tag{13}
\]
From the second equation in (13) it is clear that \((x^n_{\text{var}}, \zeta^n)\) converges to zero if and only if \((x^n_{\text{var}}, \tau^n_{\text{var}})\) converges to zero. Using (13) and (11) we have

\[
\begin{align*}
\tau_{\text{var}}^{n+1} &= \frac{A_d - 1}{B_d} (A_d x_{\text{var}}^n + B_d \tau_{\text{var}}^n) - \frac{(A_d - 1)^2}{B_d} x_{\text{var}}^n + \zeta^n \\
&= \frac{A_d - 1}{B_d} (A_d x_{\text{var}}^n - (A_d - 1) x_{\text{var}}^n + B_d \tau_{\text{var}}^n) + \tau_{\text{var}}^n - \frac{A_d - 1}{B_d} x_{\text{var}}^n \\
&= (A_d - 1) \tau_{\text{var}}^n + \tau_{\text{var}}^n \\
&= A_d \tau_{\text{var}}^n.
\end{align*}
\]

(14)

Thus the closed loop system for \(x_{\text{var}}^n\) and \(\tau_{\text{var}}^n\) is

\[
\begin{align*}
x_{\text{var}}^{n+1} &= A_d x_{\text{var}}^n + B_d \tau_{\text{var}}^n \\
\tau_{\text{var}}^{n+1} &= A_d \tau_{\text{var}}^n.
\end{align*}
\]

(15)

Since \(A_d \in (0, 1)\) this is stable. In the following section we investigate the stability of the controller (13) on the original system.

### 3 Stability analysis

In this section we prove that the controller (13) stabilizes the original system (7). The control action on the original system is modified such that realistic time switches are applied to the original system. The rules are

- If \(\tau_{\text{var}}^n + \tau_{\text{opt}} > \tau_f\), then \(\tau^n = \tau_f\)
- If \(\tau_{\text{var}}^n + \tau_{\text{opt}} < 0\), then \(\tau^n = 0\)
- If \(0 \geq \tau_{\text{var}}^n + \tau_{\text{opt}} \leq \tau_f\), then \(\tau^n = \tau_{\text{var}}^n + \tau_{\text{opt}}\).

(16)

Next we show that if \(\tau^n\) is chosen according to these rules, then \(x^n\) stays bounded. Later we show that \(x^n \to x_{\text{opt}}\).

**Lemma 3.1.** Let \(\tau^n\) be a sequence in the interval \([0, \tau_f]\) and let \(x^0\) be given. For any \(\delta > 0\) there exists a \(N\) such that \(x^N \in (-A^{-1}_d B_1 - \delta, -A^{-1}_d B_2 + \delta)\) for \(n \geq N\). Here \(x^n\) is the solution of (7).

**Proof.** See the appendix.

Using the linearized model (11) we can write (7) as

\[
x_{\text{var}}^{n+1} = A_d x_{\text{var}}^n + (B_d + \varepsilon(x_{\text{var}}^n, \tau_{\text{var}}^n)) \tau_{\text{var}}^n.
\]

(17)

Here we have used that (7) is linear in \(x\). Similar as in (14), we obtain the following difference equation for \(\tau_{\text{var}}\)

\[
\tau_{\text{var}}^{n+1} = (A_d + \frac{A_d - 1}{B_d} \varepsilon(x_{\text{var}}^n, \tau_{\text{var}}^n)) \tau_{\text{var}}^n.
\]

(18)
Here $\varepsilon$ is the error induced by linearization. Our closed loop system becomes

$$
x^n_{var} + 1 = A_d x^n_{var} + (B_d + \varepsilon(x^n_{var}, \tau^n_{var})) \tau^n_{var}
$$

$$
x^n_{var} = (A_d + \frac{A_d - 1}{B_d}) \varepsilon(x^n_{var}, \tau^n_{var}) \tau^n_{var}.
$$

(19)

We know from Lemma 3.1 that $(x^n_{var}, \tau^n_{var})$ will lie in a bounded set. Using the second equation of (19), we conclude that if $\varepsilon$ is sufficiently small, then $\tau^n_{var} \to 0$. Since $\varepsilon$ contains higher order terms, and since $\varepsilon(0, 0) = 0$, the condition that $\varepsilon$ is small in a neighbourhood of $(0, 0)$ is not a strong assumption. Concluding, we have

**Theorem 3.2.** Consider equation (19). Let $\Omega = \{(x_{var}, \tau_{var}) \mid x_{var} + x_{opt} \in [-A_1^{-1}B_1, -A_2^{-1}B_2] \text{ and } \tau_{var} + \tau_{opt} \in [0, \tau_f]\}$. If

$$
\sup_{(x_{var}, \tau_{var}) \in \Omega} \left| A_d + \frac{A_d - 1}{B_d} \varepsilon(x_{var}, \tau_{var}) \right| < 1,
$$

(20)

then (19) is asymptotically stable.

### 4 Application to food storage

In this section, the controller design and the stability analysis from the previous section are applied to a model of a bulk storage room for harvested food products.

#### 4.1 The model

In this subsection the (approximated) model that was derived and validated in [12], is described. The storage room model is divided into two parts, namely the shaft and the bulk, see Figure 1. The resulting model equations are

$$
V \frac{\partial T_0(t)}{\partial t} = -\Phi \alpha(\Phi) \left( T_a(L, t) - T_c(t) \right) + \Phi T_a(L, t) - \Phi T_0(t)
$$

(21)

$$
\frac{\partial T_a(x, t)}{\partial t} = -v \frac{\partial T_a(x, t)}{\partial x} + M_4(T_p(x, t) - T_a(x, t))
$$

(22)

$$
\frac{\partial T_p(R, x, t)}{\partial t} = A_p T_p(R, x, t) + B_p T_a(x, t)
$$

(23)

$$
T_a(0, t) = T_0(t).
$$

(24)

This will be further referred to as the *nominal system*. The control input is the air flux $\Phi(t)$ that is generated by the fan, and this switches between $\Phi_1$ and $\Phi_2$. Equation (21) describes the temperature dynamics inside the shaft. $V$ is the volume of the shaft, $T_a(L, t)$ the air temperature at the top of the bulk, $T_c(t)$ the temperature of the cooling element inside the heat exchanger, $\rho_a$ the air density, $c_a$ the heat capacity of air. The dimensionless function $\alpha$
denotes the effectiveness of the cooling device: \( \alpha = 1 \) implies that the incoming air \( T_{in}(t) \) is totally cooled down (or heated up) to \( T_c(t) \), while \( \alpha = 0 \) implies that the incoming air is not cooled at all. Here, \( \alpha \) is assumed to be constant. Equation (22) describes the temperature dynamics of the air inside the bulk. The two r.h.s. terms in equation (22) denote the convection of heat and the heat exchange between product surface and air, respectively. Here, \( x \) denotes the height in the bulk, that varies from 0 to \( L \). Further, \( M_4 = \frac{h(v)A_{ps}}{\gamma \rho_c c_a} \), with \( \gamma \) the bulk porosity, and \( A_{ps} \) the product surface area per bulk volume. The heat transfer coefficient \( h(v) \) depends on \( v \) via the implicit relation (see [14])

\[
Nu = (0.5Re^{1/2} + 0.2Re^{2/3})Pr^{1/3}
\]  

(25)

for \( 10 < Re < 10^4 \), with \( Nu, Re \) and \( Pr \) the Nusselt, Reynolds and Prandtl number, see section 6. The average velocity inside the bulk is \( v = \frac{\Phi A_f}{\gamma} \), with \( A_f \) the area of the bulk floor. Equation (23) describes the temperature dynamics of the product skin (which represents the product temperature) at height \( x \) inside the bulk. The expressions for \( A_p \) and \( B_p \) are listed in the appendix. Parameters \( a \) and \( Bi \) are respectively the heat production of the products and the Biot number. The model predictions were found to be accurate when compared to experimental results. System (21)–(24) was approximated by using timescale decomposition and transfer function approximation to

\[
\frac{dT_p(L, t)}{dt} = A(\Phi(t))T_p(L, t) + B(\Phi(t)),
\]

(26)

with \( T_p(L, t) \) the product temperature at the top of the bulk. The expressions for \( A \) and \( B \) are given in the appendix. The values of the physical parameters are listed in Table 1. In Table 2 the corresponding numerical values of the key parameters are listed.
α = 0.4
R = 3.25 \times 10^{-2} \, m
Φ_1 = 1 \, m^3/s
λ_p = 0.55 \, J/s \, m \, K
a = 3.1 \times 10^{-5} \, J/s \, kg \, K
γ = 0.39
T_c = 275 \, K
L = 4 \, m

A_f = 5 \, m
V = 10 \, m^3
Φ_2 = 0.001 \, m^3/s
ρ_p = 1014 \, kg/m^3
A_{ps} = 49 \, m^2
c_p = 3.6 \times 10^3 \, J/kg \, K
c_a = 2 \times 10^3 \, J/kg \, K

Table 1: Physical parameters of a bulk storage room with potatoes. Specific data were taken from [5, 14, 11].

| A_1 | -2 \times 10^{-3} \, 1/s |
| B_1 | 6.6 \times 10^{-3} \, K/s |
| A_d | 1.0 - 3 \times 10^{-4} |
| τ_f | 600 \, s |
| T_{p,\text{opt}} | 280 \, K |
| A_2 | -2 \times 10^{-8} \, 1/s |
| B_2 | 8.1 \times 10^{-6} \, K/s |
| B_d | -1.2 \times 10^{-4} \, K/s |
| τ_{opt} | 12.2 \, s |

Table 2: Numerical key parameter values.

### 4.2 Controller

The controller measures the product temperature at the top of the bulk, \( T_p(L, t) \). The optimal switching time corresponds to \( T_p(L, t) = T_{p,\text{opt}} \). Realistic disturbances in the air temperature \( T_0(t) \) is caused by open doors, heat leakage through the walls, etcetera. For mathematical simplicity we assume that the disturbances in air temperature occur in the vicinity of the heat exchanger, and that they therefore act on the system as the temperature of the cooling element \( T_c \). For design purposes, we look at the crossover frequency of the transfer function from \( T_c \) to \( T_p(L) \). In [12] it was shown that this transfer function has a crossover frequency of \( k = -A^*(Φ) \). For simplicity, we take the average of \( k \) w.r.t. the switching time, which gives

\[
\kappa_{av} = \frac{τ_{opt}}{τ_f} k(Φ_1) + \frac{τ_f - τ_{opt}}{τ_f} k(Φ_2). \tag{27}
\]

It turns out that this is practically the same crossover frequency as in \( G \). This means that, from a classic control design point of view, the perturbations act on the system as depicted in Figure 3. Therefore, the controller design as proposed in section 2.2 is appropriate for the bulk storage room model.

### 4.3 Stability

In this section the influence of the linearization error on the stability is investigated. We define the linearization as in (11), with the variable \( x \) replaced with \( T_p(L) \). Also, \( T_p(L) \) is denoted by \( T_p \) for convenience. We recall the system (19)
with \( x_{\text{var}} \) replaced with \( T_{p,\text{var}} \)

\[
\begin{align*}
T_{p,\text{var}}^{n+1} &= A_d T_{p,\text{var}}^n + (A_d + \varepsilon) \tau_{\text{var}}^n \\
\tau_{\text{var}}^{n+1} &= (A_d + \varepsilon) \tau_{\text{var}}^n.
\end{align*}
\] (28)

We have that

\[
\varepsilon = \frac{1}{2} \frac{\partial^2 f}{\partial T_p \partial \tau^n} (T_{p,\text{opt}}, \tau_{\text{opt}}) T_{p,\text{var}}^n + \frac{1}{2} \frac{\partial^2 f}{\partial \tau^n \partial T_p} (T_{p,\text{opt}}, \tau_{\text{opt}}) T_{p,\text{var}}^n
\]

\[+ \frac{1}{2} \frac{\partial^2 f}{\partial (\tau^n)^2} (T_{p,\text{opt}}, \tau_{\text{opt}}) \tau_{\text{var}}^n + \text{h.o.t.} \] (29)

We neglect the higher order terms of \( \varepsilon \), which gives

\[
\varepsilon = \frac{1}{2} \left( (A_1 - A_2) \alpha_2 - A_2 + A_1 \alpha_2 \right) T_{p,\text{var}}^n + \frac{1}{2} \left( (A_1 - A_2) \left( (A_1 - A_2) \alpha_2 T_{p,\text{opt}} - \frac{A_2 B_1}{A_1} \alpha_2 + B_1 \alpha_2 \right) \right.
\]

\[- \frac{1}{2} A_2 \left( \frac{A_2 B_1}{A_1} - B_2 \right) \exp(A_2(\tau_f - \tau_{\text{opt}})) \right) \tau_{\text{var}}^n,
\] (30)

with \( \alpha_2 = \exp(A_2(\tau_f - \tau_{\text{opt}}) + A_1 \tau_{\text{opt}}) \). Numerical evaluation gives

\[
\varepsilon = -2.4 \times 10^{-5} T_{p,\text{var}} + 7.9 \times 10^{-8} \tau_{\text{var}}.
\] (31)

We have that \( A_d = 1 - 3 \times 10^{-4} \), and \( B_d = 6.5 \times 10^{-3} \), so the stability criterion of Theorem 3.2 \( |A_d + \frac{A_2 A_1^{-1}}{B_2} - 1| \) becomes \( |1 - 3 \times 10^{-4} + 4.6 \times 10^{-2} \varepsilon| < 1 \), which is fulfilled if \( |\varepsilon| < 64.6 \). We have that \( 0 < \tau_{\text{var}} < 600 \), according to (16), and that \( T_p \) will converge to the range \( (-A_1^{-1} B_1 - \delta, -A_2^{-1} B_2 + \delta) \) for any \( \delta \) by Lemma 3.1. Since for our case \( (-A_1^{-1} B_1, -A_2^{-1} B_2) = (275.1, 398.2) \), we have that \( |T_{p,\text{var}}| < 123.1 \) for any choice of \( T_{p,\text{opt}} \). Altogether, \( T_{p,\text{var}} \) and \( \tau_{\text{var}} \) cannot grow large enough to destabilize the system, and hence the system is asymptotically stable according to Theorem 3.2.

### 4.4 Simulation study

In the previous section the stability robustness was analyzed, and in this section we analyze the loss of performance due to the linearization. This is done by connecting controller (36) to the linearized system (32) and to the nominal system (21)–(24). The differences in \( T_p(L, t) \) and \( \tau(t) \) should give an indication whether any essential dynamics is discarded. The two controlled systems are simulated numerically. For the spatial discretisations, a forward Euler step was used, and the dynamics in time were computed inside the Matlab Simulink environment using an ode45 Dormand-Prince algorithm. Further, a heavy input disturbance \( d \) was added, such that the system dynamics were clearly visible. The initial product temperature was set uniform at 285 K, while the optimal product temperature is 280 K. The input disturbance is \( d = a \sin(\omega t) \), with
\( a = 10 \text{ s}, \) and \( \omega = 3 \times 10^{-6} \text{ Hz}. \)

The dynamics of \( \tau(t) \) and \( T_p(L, t) \) are shown in Figure 2. For both controlled systems the dynamics of \( T_p(L, t) \) and \( \tau(t) \) are more or less the same, indicating that the approximation errors in the approximation steps from (21)–(24) to (32) do not discard any essential dynamics. Even when initially the product temperature differs considerably from the linearization point of 280 K, the differences are small. Furthermore, the controller seems to perform quite well under these large input disturbances. For various frequencies of \( d \) similar results were obtained. The differences in system dynamics increase with the amplitude, since then the linearization error becomes larger.

![Figure 2: \( T_p(L, t) \) (upper left) and \( \tau(t) \) (upper right) of the linearized controlled system, and \( T_p(L, t) \) (bottom left) and \( \tau(t) \) (bottom right) of the nominal controlled system.](image)

## 5 Conclusions

We showed that for a large class of nonlinear scalar systems with discrete input, it is possible to make an approximation that allows the design of a linear controller that controls the switching time of the input. This is done by a linearization, and the linearization points are the optimal switching time that corresponds to the optimal state, and the optimal state. Lemmas 2.1 and 3.1 give conditions for the existence of such a linearization point, state its uniqueness, and guarantee that the state is bounded. Theorem 3.2 gives the condition for asymptotic stability of the controlled system. The conditions are in analytical form, which gives a more structural insight into the influence of errors and
perturbations on the stability.

As an example, a controller was designed and connected to a temperature model of a bulk storage room. For controller design, the original (or nominal) model was linearized. It was shown that the stability cannot be jeopardized by the linearization error. Numerical simulations show that under large input disturbances the nominal and the approximated system have similar dynamics in $T_p$ and $\tau$. This also holds for different physical parameters and disturbance frequencies, indicating that the linearization does not discard any essential dynamics. Hence a controller with excellent properties can be designed for the bulk storage room model.

The linearization and the controller design can be applied to any system. However, for more complex systems, such as higher order systems, the controller design and the stability analysis do generally not result in parametric expressions, and will therefore be more numerically involved. Nevertheless, a next step would be the design of a switching input controller for higher order systems, together with a numerical stability analysis.

References

The following strategy is used. Equation (11) is approximated by a continuous system, by taking $\tau_f \rightarrow 0$. The idea is that the dynamics of $x$ are slow on $(0, \tau_f)$, and therefore $\frac{dx}{dt} \approx \frac{x^{n+1}-x^n}{\tau_f}$. We start by rewriting (11) as

$$\frac{x^{n+1}-x^n}{\tau_f} = A_{lin}x_{var}^n + B_{lin}\tau_{var}^n,$$

(32)

with $A_{lin} = \frac{A_d-1}{\tau_f}$, and $B_{lin} = \frac{B_d}{\tau_f}$. We approximate it by a continuous system, by taking $\tau_f \rightarrow 0$, so (32) becomes

$$\frac{dx_{var}(t)}{dt} = A_{lin}x_{var}(t) + B_{lin}\tau_{var}(t).$$

(33)
For (33) it is now possible to design a controller by standard linear theory. For the formulation of design specifications, system (33) is transformed into the Laplace frequency domain to

\[
\hat{x}_{\text{var}}(s) = \frac{B_{\text{lin}}}{-A_{\text{lin}} + s} \hat{\tau}_{\text{var}}(s)
\]

\[
= G(s)\hat{\tau}_{\text{var}}(s).
\]

(34)

In this section it is assumed for simplicity, that there is only one disturbance, \(d\), which acts on the input \(\tau_{\text{var}}\). Figure 3 shows the interconnection of \(G(s)\) and the controller \(K(s)\), together with the input disturbance. Various designs are possible, e.g. LQG or optimal control design. We propose the following design specifications that are standard for linear SISO systems (see for example [7] for more details).

- The sensitivity function \(S = \frac{1}{1 + K(s)G(s)}\) from \(d\) to \(x_{\text{var}}\) should be small for low frequencies, and close to 1 for high frequencies for good performance.
- A very high crossover frequency of \(S\) will result in a very fast controller, with the tradeoff that the performance and stability will be poor.

Input disturbances with a higher frequency than the crossover frequency of \(G\) are already attenuated by \(G\). Therefore, a good choice would be that \(S\) is small up to the crossover frequency of \(G\): \(-A_{\text{lin}}\). In other words, we have to find \(K\) such that

\[
\frac{1}{1 + G(s)K(s)} = \frac{\hat{s}}{1 + \hat{s}},
\]

(35)

with \(\hat{s} = \frac{s}{-A_{\text{lin}}}\). In this way, \(S_2\) is small for all frequencies, \(S\) is small for frequencies up to \(s = -A_{\text{lin}}\), and \(S\) tends to 1 for high frequencies. Straightforward calculation gives the PI controller

\[
K(s) = \frac{A_{\text{lin}} - s}{B_{\text{lin}} A_{\text{lin}}} \hat{\tau}(s)
\]

\[
\Leftrightarrow \hat{\tau}(s) = (\frac{A_{\text{lin}}}{B_{\text{lin}}} - \frac{A_{\text{lin}}}{B_{\text{lin}}}) \hat{x}_{\text{var}}(s).
\]

(36)

With the substitution

\[
\hat{\zeta}(s) = -\frac{A_{\text{lin}}^2}{B_{\text{lin}}} \hat{x}_{\text{var}}(s)
\]

(37)

our controller in discrete time becomes

\[
\frac{\zeta^{n+1} - \zeta^n}{\tau_f} = -\frac{A_{\text{lin}}^2}{B_{\text{lin}}} x_{\text{var}}^n
\]

\[
\tau_{\text{var}}^n = \zeta^n + \frac{A_{\text{lin}}}{B_{\text{lin}}} x_{\text{var}}^n.
\]

(38)

Note that the controller is an explicit parametric function of all the system characteristics. Figure 3 shows the controlled system with input disturbance \(d\) schematically.
6.2 Proofs

6.2.1 Proof of lemma 2.1

Using (6) we can write $f(x, \tau)$ as

$$f(x, \tau) = f_1(\tau)x + f_2(\tau). \quad (39)$$

Further, it is not hard to see that for $\tau \in [0, \tau_f]$ $f_1(\tau) \in (0, 1)$, and

$$f_2(0) = (\exp(A_2 \tau_f) - 1))A_2^{-1}B_2$$
$$f_1(\tau_f) = (\exp(A_1 \tau_f) - 1))A_1^{-1}B_1. \quad (40)$$

Solving

$$x_{opt} = f_1(\tau)x_{opt} + f_2(\tau) \quad (41)$$

for $\tau \in [0, \tau_f]$ is possible if and only if

$$x_{opt} = \frac{f_2(\tau)}{1 - f_1(\tau)} \quad (42)$$

is solvable for $\tau \in [0, \tau_f]$. Since the right hand side is a continuous function of $\tau$, we see that solving (42) is possible if and only if $x_{opt}$ lies in the range of $f_2/(1 - f_1)$. We have that

$$\frac{f_2(0)}{(1 - f_1(0))} = -A_2^{-1}B_2$$
$$\frac{f_2(\tau_f)}{(1 - f_1(\tau_f))} = -A_1^{-1}B_1. \quad (43)$$

Thus if $x_{opt}$ lies between these values, then (42) is solvable. If the range of $f_2/(1 - f_1)$ for $\tau \in [0, \tau_f]$ would be larger, then

$$\frac{f_2(\tau)}{(1 - f_1(\tau))} = -A_2^{-1}B_2 \quad \text{or}$$
$$\frac{f_2(\tau)}{(1 - f_1(\tau))} = -A_1^{-1}B_1 \quad (44)$$
must be solvable for at least two \( \tau \in [0, \tau_f] \). We show that this is not possible. We do this for the second equation, the first one goes similarly. Using (44) in (6) gives

\[
\xi = -A_1^{-1}B_1 \\
-A_1^{-1}B_1 = \exp(A_2(\tau_f - \tau))\xi + (\exp(A_2(\tau_f - \tau)) - 1)A_2^{-1}B_2 \\
\Leftrightarrow A_1^{-1}B_1 = \exp(A_2(\tau_f - \tau))A_1^{-1}B_1 - (\exp(A_2(\tau_f - \tau)) - 1)A_2^{-1}B_2 \\
\Leftrightarrow A_1^{-1}B_1 = (\exp(A_2(\tau_f - \tau)) - 1)(A_1^{-1}B_1 - A_2^{-1}B_2).
\]

(45)

Since \( A_1^{-1}B_1 \neq A_2^{-1}B_2 \), we must have \( \exp(A_2(\tau_f - \tau)) - 1 = 0 \), which gives \( \tau = \tau_f \). Now we will prove the uniqueness of \( \tau_{opt} \). Assume that \( \tau_1 \) and \( \tau_2 \) are times such that

\[
x_{opt} = f(x_{opt}, \tau_i) \ i = 1, 2.
\]

(46)

Assume that \( \tau_1 < \tau_2 \leq \tau_f \), and let

\[
\xi_i = \exp(A_1\tau_i)x_{opt} + A_1^{-1}B_1(\exp(A_1\tau_i) - 1) \ i = 1, 2.
\]

(47)

We observe from (6) that

\[
\xi_i + A_1^{-1}B_1 = \exp(A_1\tau_i)(x_{opt} + A_1^{-1}B_1)
\]

\[
x_{opt} + A_2^{-1}B_2 = \exp(A_2(\tau_f - \tau_i))(\xi_i + A_2^{-1}B_2)
\]

(48)

(49)

Since \( A_1 < 0 \), and since \( \tau_1 < \tau_2 \), we have by (48) and \( x_{opt} > -A_1^{-1}B_1 \) that

\[
\xi_1 + A_1^{-1}B_1 > \xi_2 + A_1^{-1}B_1
\]

(50)

This implies that

\[
\xi_2 + A_2^{-1}B_2 > \xi_1 + A_2^{-1}B_2.
\]

(51)

Now using (49) and the fact that \( \tau_f - \tau_1 > \tau_f - \tau_2 \) we find

\[
\exp(A_2(\tau_f - \tau_2))(\xi_2 + A_2^{-1}B_2) > \exp(A_2(\tau_f - \tau_1))(\xi_1 + A_2^{-1}B_2).
\]

(52)

However, both expressions must be equal to \( x_{opt} \). Hence \( \tau_1 \) cannot be unequal to \( \tau_2 \). \( \Box \)

### 6.2.2 Proof of lemma 3.1

We want to show that for some \( N \) \( x^N \in [-A_1^{-1}B_1 - \delta, -A_2^{-1}B_2 + \delta] \) for any \( \delta > 0 \). Suppose that this does not hold, then \( x^n \notin [-A_1^{-1}B_1 - \delta, -A_2^{-1}B_2 + \delta] \) for all \( n \). Suppose

\[
x^0 < -A_1^{-1}B_1 - \delta \Rightarrow (48) \xi^0 < -A_1^{-1}B_1 - \delta
\]

(53)

which implies that \( x_1 < -A_2^{-1}B_2 \). Since \( x^1 \notin [-A_1^{-1}B_1 - \delta, -A_2^{-1}B_2 + \delta] \) we have

\[
x^1 < -A_1^{-1}B_1 - \delta.
\]

(54)
Furthermore, $x^0 < x^1$. Repeating the above argument gives

$$x^0 < x^1 < x^2 \ldots x^n \leq -A_1^{-1}B_1 - \delta.$$ (55)

Hence $x^n \to x^\infty \leq -A_1^{-1}B_1 - \delta$. Similarly, $\xi^n \to \xi^\infty \leq -A_1^{-1}B_1 - \delta$. From (48) we conclude that if $x$ and $\xi$ both converge, then so does $\tau$. So $\tau^n \to \tau^\infty$.

Thus we have that $(x^\infty, \tau^\infty)$ is a fixed point that satisfies $x^\infty = f(x^\infty, \tau^\infty)$ and $x^\infty < -A_1^{-1}B_1$. Lemma 2.1 implies that $x^\infty \geq -A_1^{-1}B_1$. □

### 6.3 Parameters

- $\Phi$ air flow through shaft ($m^3/s$)
- $\alpha$ cooling effectiveness ($K$)
- $\alpha_{th}$ thermal diffusivity of air ($1.87 \times 10^{-5} m^2/s$)
- $\gamma$ porosity ($m^3/m^3$)
- $\lambda_a$ conduction of air ($2.43 \times 10^{-2} W/m K$)
- $\lambda_p$ conduction of product ($W/m K$)
- $\nu$ kinematic viscosity of air ($1.35 \times 10^{-5} m^2/s$)
- $\rho_a$ air density ($1.27 kg/m^3$)
- $\rho_p$ produce density ($kg/m^3$)
- $\tau$ switching time ($s$)
- $\tau_f$ length of switching interval ($s$)
- $A_f$ floor area of the bulk ($m^2$)
- $A_{ps}$ produce surface per bulk volume ($m^2/m^3$)
- $Bi$ Biot number $\frac{2hR}{\lambda_a}$
- $L$ bulk height ($m$)
- $L_2$ $R * \gamma(1 - \gamma)$, char. length ($m$)
- $Nu$ Nusselt number $\frac{2hR}{\lambda_a}$
- $Pr$ Prandtl number $\frac{\nu}{\alpha_m}$
- $R$ product radius ($m$)
- $Re$ Reynolds number $\frac{2hR}{\nu}$, [14]
- $T_a$ air temperature in the bulk ($K$)
- $T_c$ cooling element temperature ($K$)
- $T_{ini}$ initial temperature ($K$)
- $T_p$ produce temperature ($K$)
- $V$ volume of shaft ($m^3$)
- $a$ product heat production ($J/kg s K$)
- $b$ product heat production ($J/kg s$)
- $c_a$ heat capacity of air ($1 \times 10^3 J/kg K$)
- $c_p$ heat capacity of produce ($J/kg K$)
- $h$ heat transfer coefficient ($W/m^2 K$)
- $v$ air velocity inside the bulk ($m/s$)
